Professional Summary

Backend PHP Developer with 5+ years of experience in WordPress, Laravel, MySQL, and REST API development. Specialized in custom WordPress plugin development, WooCommerce solutions, third-party integrations, web scraping, cron job automation, database design, and scalable backend systems. Currently expanding expertise in Django, FastAPI, and AI-powered backend development, with a strong focus on automation, performance optimization, and modern web technologies.

Technical Skills

Programming Languages: PHP, JavaScript, Python
Frameworks & Tools: Laravel, CodeIgniter 3, WordPress, WooCommerce, Django, FastAPI, jQuery, Express.js, Git
Databases: MySQL, PostgreSQL
Cloud & DevOps: Docker
Operating Systems: Linux (Server Administration)

Professional Experience

Software Engineer

[EncoderIT Ltd], [Dhaka] | *[May 01,2024] – [Present]*
Delivered 100+ PHP and WordPress projects and code blocks, both small and large, ranging from custom snippets and fixes to full plugins, themes and multi-API platforms.
Music In Africa (musicinafrica.net):

- Migrated the entire Drupal site (posts, users, profiles, events and media) into a custom PHP/MySQL/WPML WordPress theme, using PHP cron batch scripts to clean and map data such as countries, social links and audio/video.
- Preserved every legacy Drupal URL by mapping each Drupal node ID to its new WordPress post, and built self-syncing MySQL cache tables to keep the high-traffic multilingual site fast without slow JOIN queries.
- Integrated the SoundCloud API with OAuth, caching the access token for its lifetime and refreshing it

automatically before expiry.

- Integrated Telegram Bot fatal error notifications.

WPSearch (wpsearch.ai, AI-powered plugin search platform):

- Designed a fuzzy search engine ranking roughly 56,000 WordPress plugins by a weighted relevance model (exact/phrase match, proximity, typo-tolerant partial matching) combined with a custom WPS quality score.
- Pre-built a compact JSON search index so results load instantly without hitting the database, mirroring the same PHP matching logic between live suggestions and the full results page, with debounced input and search history.
- Architected a 40-plus-job PHP scraping pipeline with per-job locking and dependency order that crawls and enriches the full WordPress.org plugin directory.
- Solved production IP-blocking with a local-to-production sync architecture, scraping locally with randomized delays and retry backoff, then pushing results to production in batches through a custom REST API.
- Designed the WPS Score ranking algorithm and a 1-10 security risk model built from WPScan vulnerability data, and automated AI-generated plugin verdicts, comparisons and SEO schema using OpenAI, Claude and Gemini.
- Integrated Telegram Bot fatal error notifications and real-time job completion alerts.

Setmore Scheduling:

- Built a WordPress plugin integrating the Setmore REST API for multi-step AJAX appointment booking, with OAuth token refresh and a fallback that records failed bookings for recovery.
- Wrote WP-Cron sync jobs keeping appointments and slots in custom MySQL tables, handling Stockholm timezones and Swedish holidays for fast, accurate lookups, plus an admin dashboard for API connections and service management.

Suncode IT Document Processing Platform:

- Built a WordPress plugin where customers order document-processing services: they choose a country and the services they need, upload their files and pay online with Stripe or PayPal, while admins work on each case and upload the finished documents back.
- Built country-based pricing, with variable services priced per country and fixed service packages per country, the order total updating live in the form, and pay-later with additional payments on an existing case, plus cancel and restore for both cases and services.
- Built the customer and admin case dashboards, an admin settings page for the payment keys, automatic emails to the customer and the admin at each step, and a browser-side download of all finished files as one ZIP.

FTFStyling (multi-currency, multilingual car parts, large WooCommerce store):

- Built two custom WordPress plugins that import and keep in sync a large automotive-parts WooCommerce catalogue from a remote store through the WooCommerce REST API, including complex variable products with their attributes, variations, images, brands and categories.
- Added REST webhook endpoints for product creation and updates that rebuild a product's variations, images and taxonomies when the source changes, plus scheduled price jobs that apply a percentage markup to simple and variable product prices.
- Built Brand > Model > Year vehicle-compatibility taxonomies from an API dataset, using OpenAI to fill in

missing car makers and models, and generated product descriptions, specifications and brand descriptions with GPT-4o.

- Automated image handling: watermarking product images (tracking which are done), restoring missing product and variation images from the source store, and converting uploads to WebP.
- Built a WPML and OpenAI translation plugin that duplicates and translates products, variations, taxonomies, attribute labels and Yoast SEO metadata into 5 languages by managing WPML translation IDs (TRID) in the icl_translations table, and carries later source edits into every translated version.
- Ran the heavy jobs as scheduled background tasks with file locks and transient fallback locks to stop overlapping runs on large batches, and preloaded the page cache for translated products in batches.

Tusenrose (multilingual, multi-currency, multi-domain WooCommerce system):

- Built a parent and child shop architecture in which a parent WooCommerce store holds the master catalogue and orders, and each child store on its own domain runs a data-handling plugin that imports products, categories and attributes from the parent through the WooCommerce REST API.
- Added webhook endpoints for product creation, update and deletion that rebuild variations, attributes, images, taxonomies and meta data on the child stores, and mapped gift-product links from remote to local product IDs.
- Built multi-currency pricing that converts prices from a SEK base into each store's WooCommerce currency using stored exchange rates, with a manual refresh from a rates API and a fallback rate table for Nordic and EU currencies.
- Translated products, categories and attributes for each store's language with WPML and OpenAI, running the jobs in the background with file and transient locks to prevent overlapping runs.
- Built order management across the shops: child stores send order created and updated webhooks to the parent with their source site, currency and latest order notes, the parent creates the order from the payload, and status changes and notes are sent back and applied to the matching child order without duplicating notes.
- Added a settings page for the parent URL, WooCommerce keys and OpenAI key, so the same plugin build can be installed on every domain without code changes.

Bilskydd (bilskydd.se, Swedish WooCommerce store):

- Built a custom WooCommerce theme with price-changing product add-ons, an AJAX slide-out cart, and a vehicle-registration API lookup that carries car details through cart, order and admin.

Football News Automation:

- Built a WordPress plugin that scrapes, deduplicates, translates (Google Translate API) and rewrites football news with GPT-4, auto-publishing SEO-optimized posts through a WP-Cron pipeline with an admin monitoring dashboard.

AI Meal-Planning Platform:

- Built an OpenAI-powered WordPress platform that turns user goals and voice input into personalized meal plans, with Stripe subscription billing, an affiliate program and PDF invoicing.
- Built a credit-based usage system (including HeyGen AI avatar calls) shared between parent and child accounts with double-spend guards, magic-link login, and a dashboard with 30-plus AJAX endpoints.

Spictera Usage-Based Billing Plugin:

- Built a WordPress plugin that ingests backup-server usage telemetry (device counts, storage capacity)

through an authenticated REST webhook and turns it into usage-based invoice line items against each customer's licensing agreement.
- Automated overage and growth calculations when usage reports are missing, estimating capacity growth from historical trends, and integrated with Zoho via OAuth for tax lookup and invoice generation.
- Built a role-based admin system (custom roles, company and dealer assignment, granular permissions) with per-role dashboards, license and usage charts, activity logs, and automated daily email and reporting cron jobs.

EncoderIT Website RAG:

- Built a retrieval-augmented generation (RAG) assistant for the EncoderIT website that stores post content, plus additional information entered manually, as embeddings in Pinecone so the LLM answers from the site's own content.
- Built an admin settings screen to choose which post types are synced to Pinecone, with an option to set the post meta key used for RAG.
- Added a MySQL question cache: each user question and its LLM answer are saved, the LLM also generates possible similar questions that are stored against the same answer, and every question is stored with a hash.
- Before calling the LLM, the incoming question's hash is looked up in MySQL and a stored answer is returned directly when found, which reduces LLM calls, cost and response time.

Multi-Tenant Customer Inbox for WhatsMarketing (directed AI coding agents end to end):

- Directed AI coding agents end to end, without writing code by hand, to turn the open-source Chatwoot inbox into a pure multi-tenant system: every customer is a separate company account with its own administrators, agents and inboxes, and no customer can see another customer's data.
- Managed all customers from one central panel: create a company, add its administrator and agents, and sign them in with one click, while the number of agents each company can have is set by its package, with a custom limit for special contracts.

Software Engineer

[workspaceit.com], [Dhaka] | [October, 2023] – [April, 2024]

- Built web scraping and lead generation pipelines to aggregate car data across multiple platforms; implemented Laravel Jobs, Queues, Workers, Cron scheduling, Query Caching, Raw Queries, and Eloquent ORM.

Software Engineer

[Mysoftheaven (BD) Ltd.], [Dhaka] | [June, 2022] – [October, 2023]

E-Court Management System (Executive Magistrate & Certificate Court), A2i ,Government of Bangladesh:

- Built a Laravel-based e-court platform digitising case filing, hearings, cause lists, order sheets and appeals for Executive Magistrate courts across Bangladesh's division, district and upazila offices.
- Integrated the platform with Doptor, the government's central identity system, so District Magistrates, ADMs, UNOs, Executive Magistrates and Peshkars sign in via single sign-on instead of separate passwords.

- Designed a repository-based integration layer against Doptor's REST APIs that reads each officer's office, designation and organogram data, and automatically creates or updates their local account, role and court assignment on first login.
- Connected external systems (Doptor, plus CDAP/myGov for citizen login and NID checks) without new data models or manual user setup, and added access-control middleware that revokes access as officers transfer or leave a post.
- Integrated Zoom API for virtual court hearings and osTicket for automated issue tracking and customer support management.

Tender Management System:

- Built a tender management system in PHP with CodeIgniter 3, including the create, read, update and delete (CRUD) features for managing tenders.
- Built a REST API for the system's mobile application.

Education

Degree / Program	Institution	Year
Bachelor of Engineering (BEngg), Computer Science & Engineering	Chittagong University of Engineering & Technology (CUET), Chattogram, Bangladesh	2019 (Second Division/Class)

Projects

Image Enhancement Based on Pixel Intensity Adjustment and Wiener Filter

Final Year B.Sc. Thesis, Dept. of Computer Science & Engineering, CUET | 2019

- Designed a noise-detection algorithm that classifies grayscale image regions as noisy or non-noisy from variance statistics, applying Wiener and median filtering only where needed to avoid unnecessary blurring.
- Built a low-light detection method from red-channel histogram statistics and a scaling-factor-based enhancement in the HSI color model that brightens only the intensity channel.
- Designed a contrast-enhancement algorithm in the HSI color model and combined all three methods into a single pipeline, implemented and validated in MATLAB.
